

SI 206 Final Project

Logan Hanekamp, Lucy Deerin, Julia Reel

Our Original Goals

- Use Visual Crossing Weather API, NHTSA Crash Viewer API, and Wolfram Alpha Website Search for Population
- Create at least 3 visualizations
- Use at least 2 APIs and 1 Website
- To compare the ratio of car crashes by population for each state given the average weather that year
- Learn about and visualize how the average weather each year affects the ratio of car crashes by population

Our Achieved Goals

- Used NHTSA Crash Viewer API
- Created 5 visualizations
- Used 2 APIs and 2 Websites
- Compare the number of fatal car crashes in the top 10 populated Illinois counties in 2019.
- Learn about and visualize how the average weather in 2019 affects the number of car crashes in Illinois.

APIs and Websites

- NHTSA Crash Viewer API
- Wikipedia page for list of county names in Illinois
- Website with population per county in 2019
- Weatherstack API

Data Calculated from
county_code.py

≡ total-amounts.txt ●

Users > logan-hanekamp > Desktop > SI 206 > MY FINAL PROJECT > ≡ total-amounts.txt

```
1  Total population, total amount of fatal car crashes, total snowfall (in), and average temperature in Illinois in 2019
2  =====
3
4  The total population in Illinois in 2019: 12741080
5
6  The total number of fatal crashes in Illinois in 2019: 938
7
8  The total amount of snowfall (inches) in Illinois in 2019: 4345
9
10 The average temperature (Fahrenheit) in Illinois in 2019: 55.117205479452075
11
12
```

Data Calculated in visualization2.py
from all tables

Visualizations

Fatalities From Car Crashes in the Top 10 Populated Illinois Counties in 2019

Population in the Top 10 Populated Illinois Counties in 2019

Ratio of Car Crash Fatalities by Population in 2019 in Illinois

When hovered over the county name appears

Relationship between Total Snowfall and Car Crash Fatalities in Illinois in 2019

Zoomed-In

Relationship between Total Snowfall and Car Crash Fatalities in Illinois in 2019

Relationship between Average Temperature and Car Crash Fatalities in Illinois in 2019

When hovered over the
county name appears

Zoomed-In

Relationship between Average Temperature and Car Crash Fatalities in Illinois in 2019

Instructions

Steps

1. Make sure that the “Weather_Crash_Data_Illinois.db” database does not already exist in your files. If it does, delete so it can be recreated.
2. Run the file “county.py”. This should be run five times. After five runs it will add all 102 rows of counties to the database. The database will create a table called “Counties”. This fills the table 24 at a time except for the last row because there are only 102 counties.
3. The second file to be run is “crash.py”. This should be run five times. After five runs it will add all 102 rows of counties to the database. The database will create a table called “Crashes”. This fills the table 24 at a time except for the last row because there are only 102 counties.

Steps

4. To produce the Matplotlib visualizations run the file “visualization1.py” once. This will produce 3 graphs.
5. To produce the Plotly visualizations run the file “visualization2.py”. This will produce 2 graphs. It will also create the two tables from the weather data “Total_Snow” and “Avg_Temp” with 102 county id’s and their corresponding total snowfall in inches and avg temperature in fahrenheit for the year 2019 within “Weather_Crash_Data_Illinois.db”.
6. Open up “Weather_Crash_Data_Illinois.db” to see the tables. There should be four total tables.
7. To see the calculations, open “ratio_of_fatalities.txt” and “total-amounts.txt”.

Code Documentation

county.py

```
def county_soup(filename):  
    """  
    Takes in a filename (string) as an input. Opens the file (downloaded HTML file from Wikipedia) and creates a BeautifulSoup object after  
    retrieving content from the passed in file (Wikipedia page). Parses through the BeautifulSoup object and captures the county name and  
    county ID number. Adds these to a list of tuples and returns the list of tuples looking like (county name, county ID #).  
    """  
  
def population_per_county(data):  
    """  
    Takes in no inputs. Creates a BeautifulSoup object after retrieving content from url. Parses through the BeautifulSoup object and captures  
    the population for each county (listed in alphabetical order). Returns a list of population numbers that is organized by county name alphabetically.  
    """  
  
def setUpDatabase(db_name):  
    """  
    Takes in the name of the database, a string, as the input. Returns the cursor and connection to the database.  
    """  
  
def inputCountyData(data, pop_data, curr, conn):  
    """  
    Takes in a the list of tuples with county name and county id, a list of population per county, the database cursor and the database  
    connections as inputs. Creates a table that will hold an id number, county name, county code, and that county's population. Returns nothing.  
    """  
  
def main():  
    """  
    Takes no inputs and returns nothing. Adds data to database.  
    """
```

```
def get_county_codes(curr, conn):  
    """  
    Takes in the database cursor and connection as inputs.  
    Collects all of the county codes and county_ids from the Counties table in the database.  
    Returns a list of tuples in the format (county_code, id)  
    E.g. [(1,0), (3,1)...]  
    """  
  
def create_request_url(year, county_code):  
    """  
    Takes in a year as a string and a county_code as an integer. Creates and returns the url  
    that will be processed NHTSA Crash data API.  
    """  
  
def get_crash_data(county_codes, year):  
    """  
    Takes in the county_code/id list of tuples that was returned by get_county_codes(). Takes in a year as an int.  
    Loops through the counties in the list of tuples and creates a request url. Processes the JSON data into a dictionary.  
    Creates and returns a list of tuples each containing the number of fatal crashes, county_id, year,  
    and number of total fatalities for each county.  
    """  
  
def setUpDatabase(db_name):  
    """  
    Takes in the name of the database, a string, as the input. Returns the cursor and connection to the database.  
    """  
  
def setUpCrashTable(data, curr, conn):  
    """  
    Takes in the list of tuples returned in get_crash_data() as input, along with the database cursor and connection. Inputs the data  
    into the table 25 rows at a time. Function does not return anything.  
    """  
  
def main():  
    """  
    Takes no inputs and returns nothing. Adds data to database.  
    """
```

weather.py

```
1 def create_request_url(county, list_dates):
2     """
3     Takes in a list of dates and a county name (string) as an input. Generates a url to search within the weather api using a base url in tandem with
4     parameters which are formed using the input values. It then indexes the json data returned by the search, and appends the 'historical' values of each
5     dictionary to a list, 'list_data'. It then returns this list of data, which is a list of dictionaries where the keys are the dates for every day in the year
6     2019 and the values contain the information we need for our analysis.
7
8     """
9
10 def snow_data(data):
11     """
12     Takes in a a dictionary and iterates through the keys which in our case are dates of each day in a year, and adds the total snowfall per day
13     to a variable by indexing into the dictionary and accessing the total snowfall per day. It then returns that number, which in our case is the
14     total snow fall in a year for a specific county.
15
16     """
17
18 def temp_data(data):
19     """
20     Takes in a dictionary and iterates through the keys which in our case are dates of each day in a year, and adds the avg temperature per day
21     to a variable by indexing into the dictionary and accessing the total snowfall per day. It then divides that number by the amount of items in
22     dictionary, which in our case is 365 (because there were 365 days int he year 2019) returns that number, which in our case is the
23     average temprature for the entire year of 2019 for a specific county.
24
25     """
26
27 def snow_per_county(list_counties):
28     """
29     Takes in a list of counties (a list of strings) as input and, using create_request_url, tailors the api to search for data on each county by iterating
30     through the list. It then uses snow_data to get the total snowfall for each county. It saves each county name and total snowfall for the year
31     2019 in inches to a dictionary where the keys are county names and the values are the total snowfall in inches for the given county.
32
33     """
34
35 def temp_per_county(list_counties):
36     """
37     Takes in a list of counties (a list of strings) as input and, using create_request_url, tailors the api to search for data on each county by iterating
38     through the list. It then uses temp_data to get the avg yearly temp for each county. It saves each county name and total snowfall for the year
39     2019 in inches to a dictionary where the keys are county names and the values are the total snowfall in inches for the given county.
40
41     """
```

```
43 def create_county_list(cur, conn):
44     """
45     This function generates a list of counties by pulling each county name from the "Counties" table in the database using a select statement. It
46     then appends each name to a list by indexing the tuples returned with the fetchall statement.
47
48     """
49
50 def write_snow_cache(CACHE_FNAME, list_counties):
51     """
52     This function takes a string and a list as inputs. The string is what you want to name the file you are going to write the data to. It then
53     writes the dictionary generated from snow_per_county to a json file with the name of your choice.
54
55     """
56
57 def write_temp_cache(CACHE_FNAME, list_counties):
58     """
59     This function takes a string and a list as inputs. The string is what you want to name the file you are going to write the data to. It then
60     writes the dictionary generated from plugging the list of counties into the function temp_per_county to a json file with the file name of your
61     choice.
62
63     """

Resources

DATE	ISSUE	LOCATION OF RESOURCE	RESULT
11/29	Needed to learn how to parse through a table within a pages HTML using Beautiful Soup	https://stackoverflow.com/questions/10309550/python-beautifulsoup-iterate-over-table	Used: <pre>pop_table = pop.find('tbody') pop_row = pop_table.find_all('tr')</pre> To get the specific row of content that we needed to get each county's population.
12/2	Needed to use an if statement to learn if the population only contained numbers	https://www.w3schools.com/python/ref_string_isnumeric.asp	Provided me with the <code>isnumeric()</code> method where I was able to check if a string was all numbers.
12/2	Wanted to find cool colors to make our graphs more interesting and visually appealing	https://matplotlib.org/stable/gallery/color/named_colors.html	This provided us with over 30 colors we could use for our graphs.

DATE	ISSUE	LOCATION OF RESOURCE	RESULT
12/2	We needed a way to generate a list of dates between a certain time period, taking into account things like different month/day lengths and leap years	https://docs.python.org/3/library/datetime.html	This website provided us with information about the <code>datetime</code> module, which could help us create a list of dates that we then used with our weather data collecting API.
12/6	Wanted to learn how to add fonts to our graph titles to make our graphs more interesting and visually appealing	https://stackoverflow.com/questions/21321670/how-to-change-fonts-in-matplotlib-python/40781216	Showed us how to change the font from Matplotlib's default fonts.
12/7	Wanted to make a graph so when you hover over the bar or scatter we can see the county name.	https://plotly.com/python/bar-charts/	Showed us how to create this type of feature using plotly for both of our graphs in this part.
